

Brain tissue temperature dynamics during functional activity and possibilities for optical measurement techniques

by

GREGGORY H. ROTHMEIER

Under the Direction of A. G. Unil Perera

ABSTRACT

Regional tissue temperature dynamics in the brain is determined by the balance of the metabolic heat production rate and heat exchange with blood flowing through capillaries embedded in the tissue, the surrounding tissues and the environment. Local changes in blood flow and metabolism during functional activity can upset this balance and induce transient temperature changes. Invasive experimental studies in animal models have established that the brain temperature changes during functional activity are observable and a definitive relationship exists between temperature and brain activity. Here, we present a theoretical framework that links tissue temperature dynamics with hemodynamic activity allowing us to noninvasively estimate brain temperature changes from experimentally measured blood-oxygen level dependent (BOLD) signals. With this unified approach, we are able to pinpoint the mechanisms for hemodynamic activity-related temperature increases and decreases. In addition to this, the potential uses and limitations of optical measurements including functional near-infrared spectroscopy (fNIRS) and the thermal imaging are discussed.

Dedication

This is dedicated to my parents who made me go to college and to Brooke who inspired me to go to graduate school. If I wasn't lucky enough to have all of you I would probably be working for Geek Squad.

I also want to more specifically dedicate this to my mama. I miss you and I think about you every day.

Acknowledgements

I want to thank my advisors A. G. Unil Perera and Mukesh Dhamala for their guidance and leadership through my graduate school career. Likewise, I must thank everyone in Dr. Perera's and Dr. Dhamala's labs for always being helpful over the past couple of years. Thank you.

Calculating Temperature Changes using the fMRI BOLD Response

2.1 Background

Since its invention in the 1950's [1] and later development in the 1970's [2], Magnetic Resonance Imaging (MRI) has allowed physicians and scientists a detailed view within the human body.

2.1.1 Previously Proposed Temperature Models

Current efforts to model temperature changes be can categorized into two classes. The first class approaches the problem by considering a single voxel deep within the brain (single-voxel approach) while the second approach considers the brain and head as an entire system (multi-voxel approach). Each of these methods has their own pros and cons which will be discussed below.

Single-Voxel Approach

A single-voxel model of temperature was first proposed by SOMEONE, but has been refined over the past HOWLONG years CITEABUNCH to include more terms. Although different approaches consider different contributions to the temperature change, they all narrow the problem down to a single voxel which is usually 2mm x 2mm x 2mm. By simplifying the model, the heat equation can be simplified and the calculation is much easier to undertake. However, since the brain is not homogenous, the values used for parameters such as heat production and thermal conductivity are taken from an average of the tissues. As a result, this reduces the possible accuracy of such a model when applied to a subject. The most recently published

Figure 2.1: Generation of the fMRI BOLD response from changes in neuronal activity. Black arrows indicate a causal relationship while colored dashed-arrows indicate existing models for the relationship. The orange line (●) shows the model proposed by Sotero and Iturria-Medina [3] to calculate cerebral blood flow and metabolism and the blue line (●) shows how the model proposed by Collins et al. [4] is used to calculate temperature.

iteration of a single-voxel model was published by Sotero and Iturria-Medina [3]. The basis of this model is a modification of the Penne’s Bioheat Equation [5, 3].

$$C_t \frac{dT(t)}{dt} = (\Delta H^\circ - \Delta H_b) CMRO_2 |_0 m(t) - \rho_b C_b CBF |_0 f(t)(T(t) - T_a) - \frac{C_t}{\tau} (T(t) - T_0) \quad (2.1)$$

where BLA BLA BLA. One advantage of using eq. (2.1) is that the resting state temperature can be analytically determined by substituting $\frac{dT(t)}{dt} = 0$ [3].

$$T_0 = T_a + \frac{(\Delta H^\circ - \Delta H_b) CMRO_2 |_0}{\rho_B C_B CBF |_0} \quad (2.2)$$

If the values provided in table 2.1 are substituted into eq. (2.2), a resting temperature of 37.3057°C is found. Since the resting temperature is always greater than the arterial blood temperature, it limits the ability of the model to account for all experimental results.

Table 2.1: Parameters used to solve the single-voxel Penne’s Bioheat Equation. (modified from Sotero and Iturria-Medina [3])

Parameter	Meaning	Value
T_a	Arterial blood temperature	37°C
C_{tissue}	Tissue Heat Capacity	3.664 J/(gK)
ΔH°	Enthalpy released by oxidation of glucose	4.710 ⁵ J
ΔH_b	Enthalpy used to release O ₂ from hemoglobin	2.810 ⁴ J
CMRO ₂ ₀	Cerebral metabolic rate of O ₂ consumption at rest	0.026310 ⁻⁶ mol/(gs)
CBF ₀	Cerebral blood flow at rest	0.0093 cm ³ /(gs)
ρ_b	Blood density	1.05 g/cm ³
C_B	Blood heat capacity	3.894 J/(gK)
τ	Time constant for conductive heat loss from the ROI to the surrounding tissue	190.52 s
a, b, c	Parameters of the gamma function fitted from E(f) vs. f	0.4492, 0.2216, -0.9872
A	Maximum BOLD signal change	0.22
α	Steady state flow-volume relation	0.4
β	Field-strength dependent parameter	1.5
Variable	Meaning	
m(t)	CMRO ₂ normalized to baseline	
f(t)	CBF normalized to baseline	
T(t)	Temperature	
W(t)	Lambert W Function	
$\frac{\Delta S(t)}{S_0}$	Change in BOLD signal normalized to rest	

While eq. (2.1) is appears complicated, conceptually the equation can be easily understood.

$$\text{change in temperature} = \text{heat generated by metabolism} - \text{heat lost to convection} - \text{heat lost to conduction} \quad (2.3)$$

The system is a balance between heat generation (metabolism) and heat transfer (conduction and convection). The direction of heat transfer by convection is determined by the difference between the voxel temperature and the arterial blood temperature ($T(t) - T_a$). Similarly, the direction of heat transfer by conduction is determined by the difference between the voxel temperature and the temperature of the surrounding tissue ($T(t) - T_0$). Since T_a is less than $T(0)$, an increase in blood flow ($f(t)$) will remove heat from the voxel thereby decreasing the temperature. Conversely, an increase in metabolism ($m(t)$) without a corresponding change in blood flow, will result in tissue warming.

Multi-Voxel Approach

2.2 Modeling the BOLD Response

2.3 Modeling Temperature

2.3.1 The Approach

The fundamental difference between our temperature modeling approach and the single-voxel models discussed in section 2.1.1 is that we consider the entire head. The Pennes bioheat equation (eq. (2.1)) [5, 3] includes three terms. The first and second terms describe heat generation by metabolism and heat exchange by convection to blood flow. On shorter time scales, these two terms dominate and are sufficient for determining the temperature change; however, the third term becomes important on longer time scales.

The third term describes the heat exchanged by conduction to surrounding tissues. This is a comparatively slow process, but on larger time scales determines the resting state temperature. When calculating the temperature change, it is important to first have an accurate resting state temperature. By considering the entire head, our model is able to accurately determine a resting state temperature for each voxel, enabling far more accurate temperature calculations than what is capable with single-voxel approaches. Figure 2.2 gives a schematic of the temperature calculation procedure.

At the heart of our method is a three-dimensional implementation of the Pennes bioheat equation

$$\rho c \frac{dT}{dt} = k \nabla^2 T - \rho_{blood} f(t) w c_{blood} (T - T_{blood}) + m(t) Q_m \quad (2.4)$$

where ρ is the tissue density, c is the specific heat of the voxel, k is the thermal conductivity, ρ_{blood} is the blood density, w is perfusion by blood, c_{blood} is the specific heat of blood, T_{blood} is the arterial blood temperature, and Q_m is the baseline metabolic heat production. $f(t)$ and $m(t)$ are the time-dependent changes in blood flow and metabolism. These two factors determine the short-term change in temperature and are calculated from the fMRI BOLD response.

Preparing the model of the head

In order to begin the temperature calculating procedure, a model of the head must first be created. Using SPM8 (<http://www.fil.ion.ucl.ac.uk/spm/>), we segmented a T1 contrast image of the head into five different tissue types: bone, cerebral spinal fluid, gray matter, white matter and soft tissue. It was assumed that soft tissue voxels that are incontact with air are more appropriately labeled as skin, so in total we are

Figure 2.2: The procedure used to calculate temperature from BOLD data. Orange blocks (●) represent data, the sandy-colored block (●) is a step done using SPM8 and the teal blocks (●) are steps done using a function provided within temptools (appendix A).

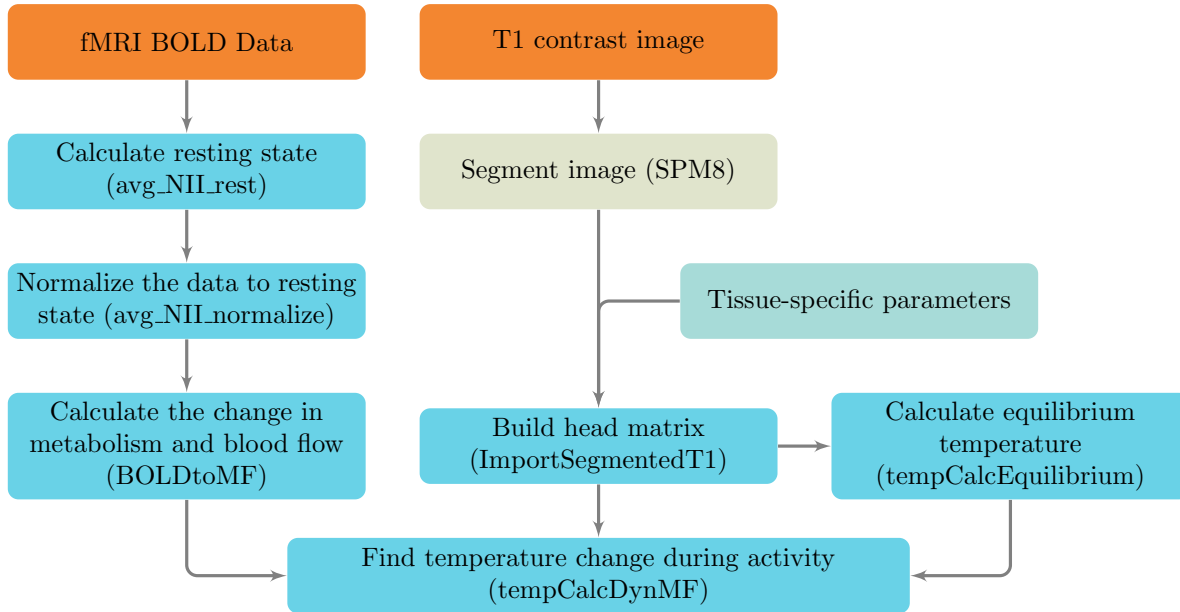

Table 2.2: Tissue-specific parameters used to calculate the temperature change (from Collins et al. [4]).

Tissue	$f_0, 100 * ml g^{-1} min^{-1}$	$\rho, kg/m^3$	$c, J kg^{-1} * ^\circ C^{-1}$	$k, W m^{-1} * ^\circ C^{-1}$	$Q_m, W/m^3$
Bone	3	1,080	2,110	0.65	26.1
Cerebrospinal Fluid	0	1,007	3,800	0.50	0
Gray Matter	67.1	1,035.5	3,680	0.565	15,575
White Matter	23.7	1,027.4	3,600	0.503	5,192
Muscle	3.8	1,041	3,720	0.4975	687
Skin	12	1,100	3,150	0.342	1,100

left with a model of the head separated in to six tissue types (fig. 2.3). The advantage this has is that we are able to use tissue specific parameters when doing the calculations, thereby improving the accuracy of the results. The parameters used are available in table 2.2. The code used to create the head matrix is discussed in appendix A.1.

Calculating the equilibrium temperature

The first step in calculating the temperature change is to first know what the resting state temperature is for each voxel within the head. Our approach was to have the initial temperature for all tissue voxels to be equal to 37°C and air voxels are kept at 24°C. The starting temperature of the tissue doesn't affect the final resting state temperature; however, starting off at drastically different values could greatly increase the calculating

Figure 2.3: Slice of the segmented head. Each color represents a different tissue type.

time required before the temperature stabilizes. The finite difference implementation of the Pennes bioheat equation (eq. (2.4)) is used to update the temperature. The temperature is updated until the temperature for every voxel has stabilized ($\frac{dT}{dt} < 10^{-6} \text{ }^{\circ}\text{C/s}$). Since temperature changes due to changes in neuronal activity are typically greater than $10^{-2} \text{ }^{\circ}\text{C}$, a change in temperature less than $10^{-6} \text{ }^{\circ}\text{C/s}$ is sufficiently small that transient temperature changes are negligible and temperature can be considered stabilized. The code used to calculate the equilibrium temperature is detailed in appendix A.3.

Calculating Metabolism and Blood Flow Changes from fMRI BOLD

This is the critical step where we use fMRI BOLD data to calculate the normalized change in metabolism and blood flow. The method used [3] is an assemblage of a couple other works [CITATION NEEDED]. The input data is a folder containing a BOLD dataset taken at equal time intervals. The first step in processing the data for temperature calculations is to determine a resting state. The resting state is calculated by taking the element-wise mean of the data when the subject is at rest (i.e. the first and last 20 seconds). This results in one data set where each voxel is a mean of all of the voxels at the location over time (S_0). In order to calculate the metabolism and blood flow, the BOLD dataset needs to be normalized to this resting

state ($S(t)/S_0$). This can then be used to calculate a BOLD-dependent variable, $y(t)$

$$y(t) = -\frac{b\beta}{\alpha + \beta c} \left[\frac{(A - \frac{S(t)}{S_0} - 1)}{Aa^\beta} \right]^{\left(\frac{1}{\alpha + \beta c}\right)} \quad (2.5)$$

where A is the maximum change in BOLD that can occur; α comes from a steady state flow-volume relation; β is a field-strength dependent parameter; and a , b , and c are parameters of the gamma function fitted from $E(f)$ vs. f (values provided in table 2.1) [3]. With $y(t)$, the change in blood flow can be calculated as follows

$$f(t) = \frac{\alpha + \beta c}{b\beta} W(y(t)) \quad (2.6)$$

where $W(y(t))$ is the Lambert-W function of $y(t)$. From $f(t)$, the change in metabolism $m(t)$ can be determined

$$m(t) = af^{c+1}(t)e^{-bf(t)}. \quad (2.7)$$

The implementation of these functions is available in appendix A.2.

Calculating the change in temperature in the active brain

2.3.2 Results

Using Theoretical BOLD Data

Using Experimental BOLD Data

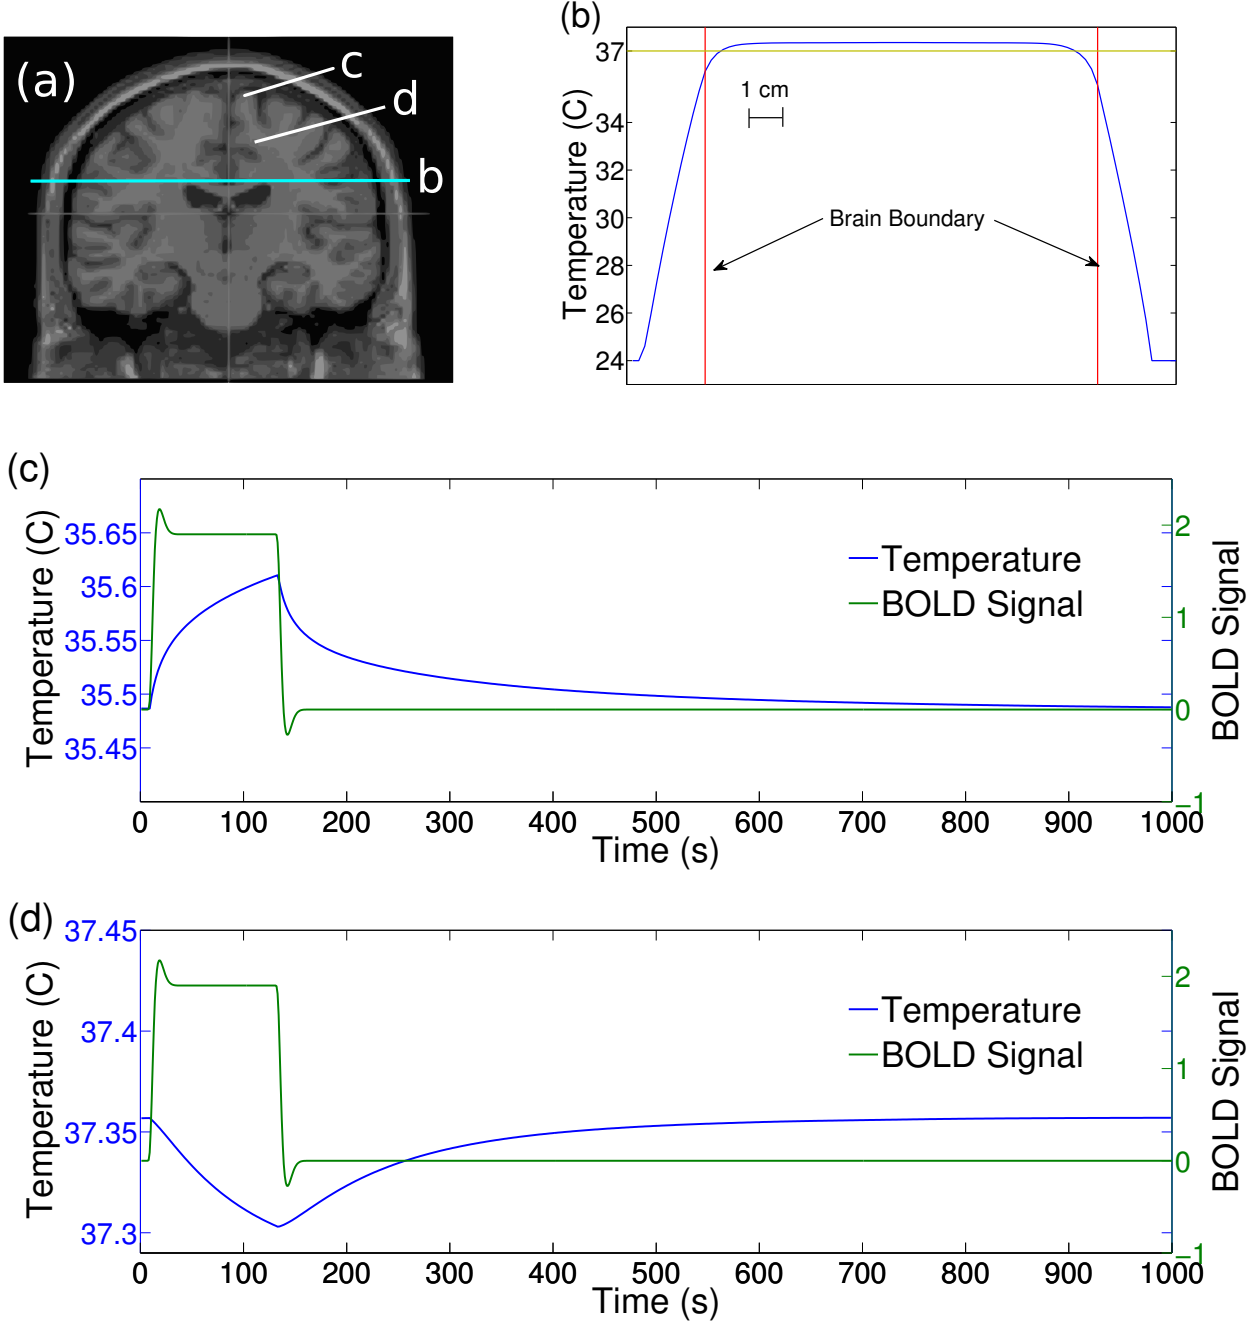

Figure 2.4: Temperature changes using simulated BOLD signals. (a) Slice of the head ($y = -12$) with indicators of the locations for parts (b)-(d). (b) Equilibrium temperature along a line through the head. Red lines indicate the brain boundary and the gold line indicates the blood temperature (37°C) used for calculations. Inside the brain, a 4-6 mm thick shell is created where the equilibrium temperature is less than the blood temperature. Within this shell, (c) the temperature rises with increased brain activity while (d) tissue deeper in the brain experiences the opposite effect.

Figure 2.5: Temperature calculated from a voxel within the motor cortex. (a) A slice ($x = -44$) showing the motor cortex warming during a finger-tapping task. (b) Temperature at a voxel within the motor cortex ($-44, -24, 60$) with standard error indicated by blue error bars (Arrows indicate task onset and conclusion, $N=24$).

Appendix A

Code

The following sections include the code used. It was written for Matlab R2011b and requires SPM8 to run. Additionally, it is recommended that you have at least 4 GB of RAM in order to work with the large datasets that are produced. For information about how to visualize the data produced, see appendix B. All of the code is available through the temptools github page (<https://github.com/greggroth/temptools>). Additionally, many of the tasks can be completed using the temptools gui (figs. A.1 to A.4) which can be invoked by running

```
temptools
```

at the Matlab command prompt (make sure the temptools directory and subdirectories have been added to the Matlab path).

Figure A.1: The main window of temptools. From here, you can go through the calculation steps and launch the visualization tool.

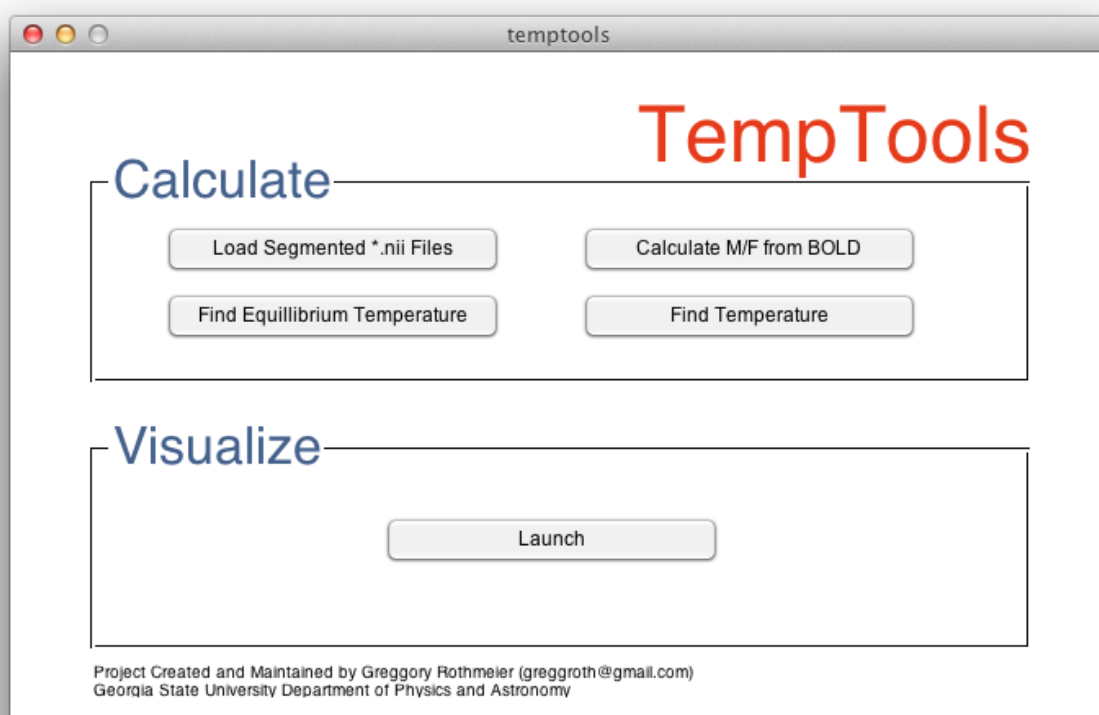

Figure A.2: This is the interface for calculating the equilibrium temperature (method explained in appendix A.3) under certain conditions.

Figure A.3: The interface for calculating temperature changes when blood flow and metabolism are time dependent. This can be achieved by either loading metabolism and blood flow datasets or by using generated activity.

The interface is titled "Temperature with Activity" and is part of a program named "findtempactivation". It contains the following elements:

- Data Loading Buttons:**
 - Load Head Data
 - Load Equilibrium Temp Data
 - Load Region of Interest
 - Load Metabolism Timecourse
 - Load Blood Flow Timecourse
- Use Generated Activity Section:**
 - Normalized Change in Metabolism: 1
 - Normalized Change in Blood Flow: 1
 - Start (Steps): 5 (1.67 s)
 - Stop (Steps): 10 (3.33 s)
 - Activation Duration: 1.67 s
- Temperature and Time Parameters:**
 - Blood Temperature: 37
 - Air temperature: 24
 - Max Time: 30
 - Step Frequency: 3
 - Save Every [6] Steps: 15 steps saved
 - Total Steps: 90
- Start Button:** A large button at the bottom labeled "Start".

Figure A.4: Visualize your data using the temptools visualization window. This loads all of the required data and launches a slice browser or tsliceplot (see appendix B for more details).

A.1 Creating the Head Matrix

Before any calculations can be done, a matrix containing tissue-specific parameters must be created. First, a T1 contrast image should be segmented using SPM8 (<http://www.fil.ion.ucl.ac.uk/spm/software/spm8/>). For ease of consistency, the one provided by SPM8 in `./canonical/` is best to use. Using SPM's "New Segmentation" algorithm will segment the image into five different tissue types (gray matter, white matter, cerebral spinal fluid, soft tissue and bone). Once this is complete, run `ImportSegmentedT1()` within this directory and it will return a matrix that has been populated with the tissue-specific parameters required for accurate temperature calculations. The functions `fillAir()` (A.1.2), `fillHoles()` (A.1.3), `build_skin()` (A.1.4) and `repair_headdata()` (A.1.5) are functions required by `BulkImportNII()`. More information about this procedure is in section 2.3.1.

A.1.1 ImportSegmentedT1()

```

A.1.5 repair_headdata()

This function will go through the dataset and make sure the tissue-specific parameters are correct for the tissue type assigned for that voxel. fillAir(), fillHoles() and build_skin() all correct mislabeled voxels, but they only correct the tissue assignment. After using any of these functions, the data must be passed through repair_headdata to update the stored parameters.

```

1 function [ head_out ] = repair_headdata( head_in )
2 % repaired_headdata repopulates the headdata matrix
3 % If any changes are made to the index column in the headdata matrix, use
4 % this function to repopulate and correct the parameter values before running
5 % any other functions.
6 % head_in can be either 3 or 4 dimenisions

```

```

A.2 Loading the fMRI Data

The following sections details the processing required to convert the BOLD data (in NIFTI format) to metabolism and blood flow time-courses that can then be used to calculate temperature.

A.2.1 sample_bold_import()

The following code automates the procedure of processing and doing all the calculations on the dataset reported in Dhamala et al. [8]. It's written for my data on my machine, but it can be used to gain a better understanding of the procedure. For a conceptual explanation, see section 2.3.1.

```

A.2.5 lambw() and lambw_mex()

The `lambw()` function is a wrapper for the `wapr()` function available on Matlab FileExchange (<http://www.mathworks.com/matlabcentral/fileexchange/3644-real-values-of-the-lambert-w-function/content/Lambert/wapr.m>). A compiled version of this function (`lambw_mex()`) runs much faster and is recommended. This function is used over Matlab's built-in Lambert-W function for the sake of performance.

```

1 function [ array_out ] = lambw( array_in )
2 % lambw Wrapper for wapr()
3 % Available:  http://www.mathworks.com/matlabcentral/fileexchange/3644-real-values
    -of-the-lambert-w-function/content/Lambert/wapr.m

```

```

4  %   Dwapr() doesn't work any arrays over Nx1, so this steps through the
5  %   full matrix and gives the rows to wapr. Works pretty fast.
6
7  %#codegen
8
9  if ndims(array_in) ~= 3
10     error('This only works (for now) with a three dimensional array.')
11 end
12
13 xmax = size(array_in,1);
14 ymax = size(array_in,2);
15
16 array_out = zeros(size(array_in));
17 for ix=1:xmax
18     for iy=1:ymax
19         array_out(ix,iy,:) = wapr(array_in(ix,iy,:));
20     end
21 end
22
23 end

```

A.3 Calculating the Equilibrium Temperature

In order to determine the temperature fluctuations due to changes in activity, the baseline temperature must first be established for each voxel. The function `tempCalcEquilibrium()` will update the temperature using the Penne's bioheat equation (eq. (2.4)) until the change in temperature for each voxel falls below a certain threshold. Details about this procedure are available in section 2.3.1.

A.3.1 `tempCalcEquilibrium()`

```
1  function temperature_Out = tempCalcEquilibrium(tissue,bloodT,airT,nt,tmax,
    pastCalc,printprogress)
2  % tempCalcEquilibrium Find the equilibrium values
3  %   tissue: holds all of the structural information
4  %   bloodT: Temperature of the blood
5  %   airT:   Temperature of the surrounding air
6  %   nt:     Max number of time steps
7  %   tmax:   Total amount of time the simulation should run over
8  %
9  %   This is based off of tempCalc() but loops until the rate of change of
10 %   a each voxel is sufficiently small then outputs what's
11 %   calculated. If it takes too long to do all at once, split it up into
12 %   smaller time chunks and use the last step from the previous dataset as
13 %   pastCalc in order to resume.
14 %
15 %   Note: This does not save the time course because it can take a lot of steps to
16 %   find the equilibrium. It outputs the last time step.

Appendix B

Visualization Tools

The temperature data is a four dimensional dataset (time, x, y and z), so good visualizations tools are necessary to analyzing the results. The primary tool I use is a modification of SliceBrowser (<http://www.mathworks.com/matlabcentral/fileexchange/20604>) and is provided as part of temptools (<https://github.com/greggroth/temptools/tree/master/lib/SliceBrowser>). In working with this, I also created a function (TempPlot()) to act as a wrapper and handle possible plotting situations depending on the number of inputs.

B.0.2 TempPlot()

```
1 function [ ] = TempPlot( head, tempdata, highlightRegion, slice, equil,threshold,
    point)
2 %TempPlot Plot data from tempCalc() or BulkImportNII()
3 % INPUT TempPlot(structureddata)
4 % TempPlot(structureddata,temperaturedata)
5 % TempPlot(structureddata,temperaturedata,highlightRegion)
6 % TempPlot(structureddata,temperaturedata,highlightRegion,slice)
7 % TempPlot(structureddata,temperaturedata,highlightRegion,slice,
    EquillibriumData)
8 %
9 % This function with determine which type of data it is and then plot it
10 % appropriately.
11 %
12 % equil - Equillibrium state data
```

```

13 % threshold - threshold value for being displayed as an overlay
14 % REQUIRES: SliceBrowser (http://www.mathworks.com/matlabcentral/fileexchange/20604)
15 %% Error checking and data restructuring where necessary
16 if ndims(head) == 4
17     head = head(:,:, :,1);
18 elseif ndims(head) ~= 3
19     error('Input ''head'' must have either 3 or 4 dimensions');
20 end
21
22 if nargin > 1
23     if ndims(tempdata) == 3 % should only happen when comparing two equilibrium
        datasets
24     temp = tempdata;
25     tempdata = zeros([1 size(temp)]);
26     tempdata(1,:,:,) = temp;
27 elseif ndims(tempdata) ~= 4
28     error('Input ''tempdata'' must have either 3 or 4 dimensions');
29 end
30 tempdataShort = squeeze(tempdata(end,:,:,:));
31 end
32
33 if nargin > 2
34     if ndims(highlightRegion) ~= 3
35         error('Input ''highlightRegion'' must have 3 dimensions');
36     end
37     if size(highlightRegion) ~= size(head)
38         error('Input ''highlightRegion'' must be of the same size as ''head''');
39     end
40     tempdataShort = squeeze(tempdata(end,:,:,:));
41 end
42
43 if nargin > 3
44     if slice > size(tempdata,1)

```

```

45     error('Input ''slice'' must be less or equal to the length of the first
        dimension of ''tempdata''');
46 end
47 tempdataShort = squeeze(tempdata(slice,:,:,:));
48 end
49
50 if nargin > 4
51     if ndims(equil) == 3
52         eq = equil;
53     elseif ndims(equil) == 4
54         eq = squeeze(equil(1,:,:,:));
55     else
56         error('Input ''equil'' must have either 3 or 4 dimensions');
57     end
58     clear 'equil';
59 end
60
61 %% Pick how to format the call of SliceBrowser()
62 switch nargin
63     case 1
64         SliceBrowser(head,1,head);
65         colormap(gray);
66     case 2
67         %%SliceBrowser(squeeze(tempdata(size(tempdata,1),,:,:)),tempdata,head);
68         SliceBrowser(tempdataShort,tempdata,head);
69     case 3
70         SliceBrowser(tempdataShort,tempdata,head,highlightRegion);
71     case 4
72         SliceBrowser(tempdataShort,tempdata,head,highlightRegion);
73     case 5
74         SliceBrowser(tempdataShort-eq,tempdata,head,highlightRegion);
75     case 6
76         SliceBrowserOverlay(tempdataShort-eq,tempdata,head,highlightRegion,threshold);
77     case 7
78         imgoverlay(head,tempdataShort-eq,point,threshold)

```

```

79 | end
80 |
81 | end

```

B.0.3 tsliceplot

This is a visualization tool I wrote that allows you to view the change in temperature versus time for a line passing through the head. Screenshots of the tool can be seen in figs. B.1 and B.2.

Usage:

```
tsliceplot(temperature_data, equilibrium_temperature_data)
```

The script is available as part of temptools (<https://github.com/greggroth/temptools/tree/master/lib/tsliceplot>).

Figure B.1: Experimental data for activity in the motor cortex visualized with tsliceplot.

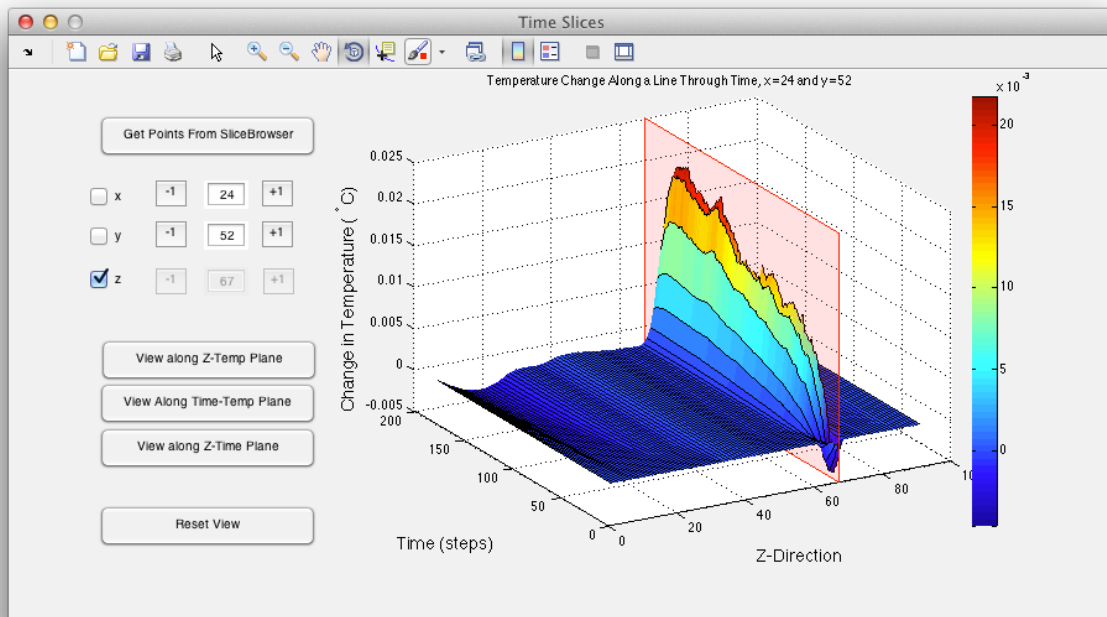

Figure B.2: The same data as is presented in fig. B.1, but viewed flat-on along the z vs. time plane.
